

---

**aspectlib**

*Release 1.0*

May 10, 2014

`aspectlib` is an aspect-oriented programming, monkey-patch and decorators library. It is useful when changing behavior in existing code is desired.

---

## Introduction

---

*aspectlib* provides two core tools to do AOP: Aspects and a weaver.

### 1.1 The aspect

An *aspect* can be created by decorating a generator with an `Aspect`. The generator yields *advices* - simple behavior changing instructions.

An `Aspect` instance is a simple function decorator. Decorating a function with an *aspect* will change the function's behavior according to the *advices* yielded by the generator.

Example:

```
@aspectlib.Aspect
def strip_return_value():
    result = yield aspectlib.Proceed
    yield aspectlib.Return(result.strip())

@strip_return_value
def read(name):
    return open(name).read()
```

You can use these *advices*:

- `Proceed` or `None` - Calls the wrapped function with the default arguments. The *yield* returns the function's return value or raises an exception. Can be used multiple times (will call the function multiple times).
- `Proceed(*args, **kwargs)` - Same as above but with different arguments.
- `Return` - Makes the wrapper return `None` instead. If `aspectlib.Proceed` was never used then the wrapped function is not called. After this the generator is closed.
- `Return(value)` - Same as above but returns the given `value` instead of `None`.
- `raise exception` - Makes the wrapper raise an exception.

### 1.2 The weaver

Patches classes and functions with the given *aspect*. When used with a class it will patch all the methods. In AOP parlance these patched functions and methods are referred to as *cut-points*.

Returns a `Rollback` object that can be used a context manager. It will undo all the changes at the end of the context.

Example:

```
@aspectlib.Aspect
def mock_open():
    yield aspectlib.Return(StringIO("mystuff"))

with aspectlib.weave(open, mock_open):
    assert open("/doesnt/exist.txt").read() == "mystuff"
```

You can use `aspectlib.weave()` on: classes, instances, builtin functions, module level functions, methods, classmethods, staticmethods, instance methods etc.

---

## Installation

---

```
pip install aspectlib
```

Or, if you live in the stone age:

```
easy_install aspectlib
```

For your convenience there is a [python-aspectlib](#) meta-package that will just install `aspectlib`, in case you run `pip install python-aspectlib` by mistake.

### 2.1 Requirements

**OS** Any

**Runtime** Python 2.6, 2.7, 3.3, 3.4 or PyPy

Python 3.2, 3.1 and 3.0 are *NOT* supported (some objects are too crippled).

---

## Testing with `aspectlib.test`

---

### 3.1 Spy & mock toolkit: `record/mock` decorators

Lightweight spies and mock responses

Example usage, suppose you want to test this class:

```
>>> class ProductionClass(object):
...     def method(self):
...         return 'stuff'
>>> real = ProductionClass()
```

With `aspectlib.test.mock` and `aspectlib.test.record`:

```
>>> from aspectlib import weave, test
>>> patch = weave(real.method, [test.mock(3), test.record])
>>> real.method(3, 4, 5, key='value')
3
>>> assert real.method.calls == [(real, (3, 4, 5), {'key': 'value'})]
```

As a bonus, you have an easy way to rollback all the mess:

```
>>> patch.rollback()
>>> real.method()
'stuff'
```

With `mock`:

```
>>> from mock import Mock
>>> real = ProductionClass()
>>> real.method = Mock(return_value=3)
>>> real.method(3, 4, 5, key='value')
3
>>> real.method.assert_called_with(3, 4, 5, key='value')
```

### 3.2 Capture-replay toolkit: `Story` and `Replay`

Elaborate tools for testing difficult code

Writing tests using the `Story` is viable when neither `integration tests` or `unit tests` seem adequate:

- Integration tests are too difficult to integrate in your test harness due to automation issues, permissions or plain lack of performance.

- Unit tests are too difficult to write due to design issues (like too many dependencies, dependency injects is too hard etc) or take too much time to write to get good code coverage.

The `Story` is the middle-ground, bringing those two types of testing closer. It allows you to start with *integration tests* and later *mock/stub* with great ease all the dependencies.

**Warning:** The `Story` is not intended to patch and mock complex libraries that keep state around. E.g.: `requests` keeps a connection pool around - there are [better choices](#).

---

**Note:** Using the `Story` on imperative, stateless interfaces is best.

---

### 3.2.1 An example: mocking out an external system

Suppose we implement this simple GNU `tree` clone:

```
>>> import os
>>> def tree(root, prefix=''):
...     if not prefix:
...         print("%s%s" % (prefix, os.path.basename(root)))
...     for pos, name in reversed(list(enumerate(sorted(os.listdir(root), reverse=True)))):
...         print("%s%s%s" % (prefix, "-- " if pos else "-- ", name))
...         absname = os.path.join(root, name)
...         if os.path.isdir(absname):
...             tree(absname, prefix + ("|  " if pos else "  "))
```

Lets suppose we would make up some directories and files for our tests:

```
>>> os.makedirs('some/test/dir')
>>> os.makedirs('some/test/empty')
>>> with open('some/test/dir/file.txt', 'w') as fh:
...     pass
```

And we'll assert that `tree` has this output:

```
>>> tree('some')
some
-- test
  -- dir
  |  -- file.txt
  -- empty
```

But now we're left with some garbage and have to clean it up:

```
>>> import shutil
>>> shutil.rmtree('some')
```

This is not very practical - we'll need to create many scenarios, and some are not easy to create automatically (e.g: tests for permissions issues - not easy to change permissions from within a test).

Normally, to handle this we'd have to manually monkey-patch the `os` module with various mocks or add dependency-injection in the `tree` function and inject mocks. Either approach we'll leave us with very ugly code.

With dependency-injection `tree` would look like this:

```
def tree(root, prefix='', basename=os.path.basename, listdir=os.listdir, join=os.path.join, isdir=os
...

```

One could argue that this is overly explicit, and the function's design is damaged by testing concerns. What if we need to check for permissions? We'd have to extend the signature. And what if we forget to do that? In some situations one cannot afford all this (re-)engineering (e.g: legacy code, simplicity goals etc).

The `aspectlib.test.Story` is designed to solve this problem in a neat way.

We can start with some existing test data in the filesystem:

```
>>> os.makedirs('some/test/dir')
>>> os.makedirs('some/test/empty')
>>> with open('some/test/dir/file.txt', 'w') as fh:
...     pass
```

Write an empty story and examine the output:

```
>>> from aspectlib.test import Story
>>> with Story(os, methods="^(?!error)[a-z]+$") as story:
...     pass
>>> with story.replay(strict=False) as replay:
...     tree('some')
some
-- test
  -- dir
  |   -- file.txt
  -- empty
STORY/REPLAY DIFF:
--- expected...
+++ actual...
@@ -...,0 +1,9 @@
+os.getpid() == ... # returns
+os.listdir('some') == ['test'] # returns
+os.stat('some/test') == os.stat_result(...) # returns
+os.listdir('some/test') == [...'dir'...] # returns
+os.stat('some/test/dir') == os.stat_result(...) # returns
+os.listdir('some/test/dir') == ['file.txt'] # returns
+os.stat('some/test/dir/file.txt') == os.stat_result(...) # returns
+os.stat('some/test/empty') == os.stat_result(...) # returns
+os.listdir('some/test/empty') == [] # returns
```

We can quickly get whatever we would need to put in the story with `aspectlib.test.Replay.unexpected`:

```
>>> print(replay.unexpected())
os.getpid() == ... # returns
os.listdir('some') == ['test'] # returns
os.stat('some/test') == os.stat_result(...) # returns
os.listdir('some/test') == [...'dir'...] # returns
os.stat('some/test/dir') == os.stat_result(...) # returns
os.listdir('some/test/dir') == ['file.txt'] # returns
os.stat('some/test/dir/file.txt') == os.stat_result(...) # returns
os.stat('some/test/empty') == os.stat_result(...) # returns
os.listdir('some/test/empty') == [] # returns
```

Now we can remove the test directories and fill the story:

```
>>> import shutil
>>> shutil.rmtree('some')
```

The story:

```
>>> with Story(os, methods="^(?!error)[a-z]+$") as story:
...     os.getpid() == 13030
...     os.listdir('some') == ['test']
...     os.stat('some/test') == os.stat_result((16893, 6691875, 2049, 3, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test') == ['empty', 'dir'] # returns
...     os.stat('some/test/dir') == os.stat_result((16893, 6691876, 2049, 2, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test/dir') == ['file.txt']
...     os.stat('some/test/dir/file.txt') == os.stat_result((33204, 6691877, 2049, 1, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.stat('some/test/empty') == os.stat_result((16893, 6691877, 2049, 2, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test/empty') == [] # returns
```

And the *strict* replay:

```
>>> with story.replay(proxy=False) as replay:
...     tree('some')
some
-- test
  -- dir
  |   -- file.txt
  -- empty
```

If we diverge a bit from the story (or we'd have some unexpected change in the `tree` function) we'd get something like this:

```
>>> with Story(os, methods="^(?!error)[a-z]+$") as story:
...     os.getpid() == 13030
...     os.listdir('some') == ['test']
...     os.listdir('bogus') == ['some bogus directory']
...     os.stat('some/test') == os.stat_result((16893, 6691875, 2049, 3, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test') == ['empty', 'dir'] # returns
...     os.stat('some/test/dir') == os.stat_result((16893, 6691876, 2049, 2, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test/dir') == ['file.txt']
...     os.stat('some/test/dir/file.txt') == os.stat_result((33204, 6691877, 2049, 1, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.stat('some/test/empty') == os.stat_result((16893, 6691877, 2049, 2, 1000, 1000, 4096, 1399131539, 1399131539))
...     os.listdir('some/test/empty') == [] # returns
>>> with story.replay(proxy=False) as replay:
...     tree('some')
Traceback (most recent call last):

```

---

## Rationale

---

There are perfectly sane use cases for monkey-patching (aka *weaving*):

- Instrumenting existing code for debugging, profiling and other measurements.
- Testing less flexible code. In some situations it's infeasible to use dependency injection to make your code more testable.

Then in those situations:

- You would need to handle yourself all different kinds of patching (patching a module is different than patching a class, a function or a method for that matter). `aspectlib` will handle all this gross patching mumbo-jumbo for you, consistently, over many Python versions.
- Writing the actual wrappers is repetitive, boring and error-prone. You can't reuse wrappers but *you can reuse function decorators*.

---

## Frequently asked questions

---

### 5.1 Why is it called weave and not patch ?

Because it does more things than just patching. Depending on the *target* object it will patch and/or create one or more subclasses and objects.

### 5.2 Why doesn't aspectlib implement AOP like in framework X and Y ?

Some frameworks don't resort to monkey patching but instead force the user to use ridiculous amounts of abstractions and wrapping in order to make weaving possible. Notable example: [spring-python](#).

For all intents and purposes I think it's wrong to have such high amount of boilerplate in Python.

Also, `aspectlib` is targeting a different stage of development: the maintenance stage - where the code is already written and needs additional behavior, in a hurry :)

Where code is written from scratch and AOP is desired there are better choices than both `aspectlib` and `spring-python`.

### 5.3 Why was aspectlib written ?

`aspectlib` was initially written because I was tired of littering other people's code with prints and logging statements just to fix one bug or understand how something works. `aspectlib.debug.log` is `aspectlib`'s *crown jewel*. Of course, `aspectlib` has other applications, see the *Rationale*.

## 6.1 Retry decorator

TODO: Make a more configurable retry decorator and add it in `aspectlib.contrib`.

```
class Client(object):
    def __init__(self, address):
        self.address = address
        self.connect()
    def connect(self):
        # establish connection
    def action(self, data):
        # do some stuff

def retry(retries=(1, 5, 15, 30, 60), retry_on=(IOError, OSError), prepare=None):
    assert len(retries)

    @aspectlib.Aspect
    def retry_aspect(*args, **kwargs):
        durations = retries
        while True:
            try:
                yield aspectlib.Proceed
                break
            except retry_on as exc:
                if durations:
                    logging.warn(exc)
                    time.sleep(durations[0])
                    durations = durations[1:]
                if prepare:
                    prepare(*args, **kwargs)
            else:
                raise

        return retry_aspect

    return retry_aspect
```

Now patch the `Client` class to have the retry functionality on all its methods:

```
aspectlib.weave(Client, retry())
```

or with different retry options (reconnect before retry):

```
aspectlib.weave(Client, retry(prepare=lambda self, *_: self.connect()))
```

or just for one method:

```
aspectlib.weave(Client.action, retry())
```

You can see here the advantage of having reusable retry functionality. Also, the retry handling is decoupled from the Client class.

## 6.2 Debugging

... those damn sockets:

```
>>> import aspectlib, socket, sys
>>> with aspectlib.weave(
...     socket.socket,
...     aspectlib.debug.log(
...         print_to=sys.stdout,
...         stacktrace=None,
...     ),
...     lazy=True,
... ):
...     s = socket.socket()
...     s.connect(('example.com', 80))
...     s.send(b'GET / HTTP/1.1\r\nHost: example.com\r\n\r\n')
...     s.recv(8)
...     s.close()
...
{socket...}.connect(('example.com', 80))
{socket...}.connect => None
{socket...}.send(...'GET / HTTP/1.1\r\nHost: example.com\r\n\r\n')
{socket...}.send => 37
37
{socket...}.recv(8)
{socket...}.recv => ...HTTP/1.1...
...'HTTP/1.1'
...
```

The output looks a bit funky because it is written to be run by `doctest` - so you don't use broken examples :)

## 6.3 Testing

Mock behavior for tests:

```
class MyTestCase(unittest.TestCase):

    def test_stuff(self):

        @aspectlib.Aspect
        def mock_stuff(self, value):
            if value == 'special':
                yield aspectlib.Return('mocked-result')
            else:
                yield aspectlib.Proceed
```

```
with aspectlib.weave(foo.Bar.stuff, mock_stuff):  
    obj = foo.Bar()  
    self.assertEqual(obj.stuff('special'), 'mocked-result')
```

## 7.1 aspectlib

---

<code>aspectlib.ALL_METHODS</code>	Compiled regular expression objects
<code>aspectlib.NORMAL_METHODS</code>	Compiled regular expression objects
<code>aspectlib.weave</code>	Send a message to a recipient
<code>aspectlib.Rollback</code>	When called, rollbacks all the patches and changes the <code>weave()</code> has done.
<code>aspectlib.Aspect</code>	Container for the advice yielding generator.
<code>aspectlib.Proceed</code>	Instructs the Aspect Calls to call the decorated function.
<code>aspectlib.Return</code>	Instructs the Aspect to return a value.

---

**class** `aspectlib.Aspect` (*advising\_function*)

Container for the advice yielding generator. Can be used as a decorator on other function to change behavior according to the advices yielded from the generator.

**class** `aspectlib.Proceed` (*\*args, \*\*kwargs*)

Instructs the Aspect Calls to call the decorated function. Can be used multiple times.

If not used as an instance then the default args and kwargs are used.

**class** `aspectlib.Return` (*value*)

Instructs the Aspect to return a value.

**class** `aspectlib.Rollback` (*rollback=None*)

When called, rollbacks all the patches and changes the `weave()` has done.

`__enter__()`

Returns self.

`__exit__(*_)`

Performs the rollback.

`rollback(*_)`

Alias of `__exit__`.

`__call__(*_)`

Alias of `__exit__`.

`aspectlib.ALL_METHODS` **Weave all magic methods. Can be used as the value for methods argument in weave.**

Compiled regular expression objects

`aspectlib.NORMAL_METHODS` **Only weave non-magic methods. Can be used as the value for methods argument in weave.**

Compiled regular expression objects

`aspectlib.weave` (*target*, *aspect* [, *subclasses=True*, *methods=NORMAL\_METHODS*, *lazy=False*,  
*aliases=True* ])  
Send a message to a recipient

**Parameters**

- **target** (`aspectlib.Aspect`, function decorator or list of) – The object to weave.
- **aspects** – The aspects to apply to the object.
- **subclasses** (*bool*) – If `True`, subclasses of target are weaved. *Only available for classes*
- **aliases** (*bool*) – If `True`, aliases of target are replaced.
- **lazy** (*bool*) – If `True` only target's `__init__` method is patched, the rest of the methods are patched after `__init__` is called. *Only available for classes.*
- **methods** (*list or regex or string*) – Methods from target to patch. *Only available for classes*

**Returns** `aspectlib.Rollback` instance

**Raises `TypeError`** If target is a unacceptable object, or the specified options are not available for that type of object.

Changed in version 0.4.0: Replaced *only\_methods*, *skip\_methods*, *skip\_magicmethods* options with *methods*. Renamed *on\_init* option to *lazy*. Added *aliases* option. Replaced *skip\_subclasses* option with *subclasses*.

## 7.2 aspectlib.debug

---

<code>aspectlib.debug.log</code>	Decorates <i>func</i> to have logging.
<code>aspectlib.debug.format_stack</code>	Returns a one-line string with the current callstack.
<code>aspectlib.debug.frame_iterator</code>	Yields frames till there are no more.
<code>aspectlib.debug.strip_non_ascii</code>	Convert to string (using <i>str</i> ) and replace non-ascii characters with a dot (.).

---

`aspectlib.debug.format_stack` (*skip=0*, *length=6*, *\_sep=''*)  
Returns a one-line string with the current callstack.

`aspectlib.debug.frame_iterator` (*frame*)  
Yields frames till there are no more.

`aspectlib.debug.log` (*func=None*, *stacktrace=10*, *stacktrace\_align=60*, *attributes=()*, *module=True*,  
*call=True*, *call\_args=True*, *call\_args\_repr=<built-in function repr>*, *result=True*,  
*exception=True*, *exception\_repr=<built-in function repr>*, *result\_repr=<function strip\_non\_ascii at 0x305c668>*,  
*use\_logging='CRITICAL'*, *print\_to=None*)  
Decorates *func* to have logging.

**Parameters**

- **func** (*function*) – Function to decorate. If missing log returns a partial which you can use as a decorator.
- **stacktrace** (*int*) – Number of frames to show.
- **stacktrace\_align** (*int*) – Column to align the framelist to.
- **attributes** (*list*) – List of instance attributes to show, in case the function is a instance method.
- **module** (*bool*) – Show the module.

- **call** (*bool*) – If True, then show calls. If False only show the call details on exceptions (if exception is enabled) (default: True)
- **call\_args** (*bool*) – If True, then show call arguments. (default: True)
- **call\_args\_repr** (*bool*) – Function to convert one argument to a string. (default: repr)
- **result** (*bool*) – If True, then show result. (default: True)
- **exception** (*bool*) – If True, then show exceptions. (default: True)
- **exception\_repr** (*function*) – Function to convert an exception to a string. (default: repr)
- **result\_repr** (*function*) – Function to convert the result object to a string. (default: strip\_non\_ascii - like str but nonascii characters are replaced with dots.)
- **use\_logging** (*string*) – Emit log messages with the given loglevel. (default: "CRITICAL")
- **print\_to** (*fileobject*) – File object to write to, in case you don't want to use logging module. (default: None - printing is disabled)

**Returns** A decorator or a wrapper.

Example:

```
>>> @log(print_to=sys.stdout)
... def a(weird=False):
...     if weird:
...         raise RuntimeError('BOOM!')
>>> a()
a()
a => None
>>> try:
...     a(weird=True)
... except Exception:
...     pass # naughty code !
a(weird=True)
a ~ raised RuntimeError('BOOM!')
```

You can conveniently use this to logs just errors, or just results, example:

```
>>> import aspectlib
>>> with aspectlib.weave(float, log(call=False, result=False, print_to=sys.stdout)):
...     try:
...         float('invalid')
...     except Exception as e:
...         pass # naughty code !
float('invalid')
float ~ raised ValueError(...float...invalid...)
```

This makes debugging naughty code easier.

PS: Without the weaving it looks like this:

```
>>> try:
...     log(call=False, result=False, print_to=sys.stdout)(float)('invalid')
... except Exception:
...     pass # naughty code !
float('invalid')
float ~ raised ValueError(...float...invalid...)
```

Changed in version 0.5.0: Renamed *arguments* to *call\_args*. Renamed *arguments\_repr* to *call\_args\_repr*. Added *call* option.

```
aspectlib.debug.strip_non_ascii(val)
    Convert to string (using str) and replace non-ascii characters with a dot (.).
```

## 7.3 aspectlib.test

This module aims to be a lightweight and flexible alternative to the popular `mock` framework and more.

---

<code>aspectlib.test.record</code>	Factory or decorator (depending if <i>func</i> is initially given).
<code>aspectlib.test.mock</code>	Factory for a decorator that makes the function return a given <i>return_value</i> .
<code>aspectlib.test.Story</code>	This a simple yet flexible tool that can do “capture-replay mocking” or “test doubles” <sup>1</sup> .
<code>aspectlib.test.Replay</code>	Object implementing the <i>replay transaction</i> .

---

```
aspectlib.test.record(func=None, recurse_lock_factory=<function allocate_lock at 0x336bb18>,
                    **options)
    Factory or decorator (depending if func is initially given).
```

### Parameters

- **callback** (*list*) – An a callable that is to be called with *instance*, *function*, *args*, *kwargs*.
- **calls** (*list*) – An object where the *Call* objects are appended. If not given and *callback* is not specified then a new list object will be created.
- **iscalled** (*bool*) – If `True` the *func* will be called. (default: `False`)
- **extended** (*bool*) – If `True` the *func*’s `__name__` will also be included in the call list. (default: `False`)
- **results** (*bool*) – If `True` the results (and exceptions) will also be included in the call list. (default: `False`)

**Returns** A wrapper that has a *calls* property.

The decorator returns a wrapper that records all calls made to *func*. The history is available as a `call` property. If access to the function is too hard then you need to specify the history manually.

Example:

```
>>> @record
... def a(x, y, a, b):
...     pass
>>> a(1, 2, 3, b='c')
>>> a.calls
[Call(self=None, args=(1, 2, 3), kwargs={'b': 'c'})]
```

Or, with your own history list:

```
>>> calls = []
>>> @record(calls=calls)
... def a(x, y, a, b):
...     pass
>>> a(1, 2, 3, b='c')
>>> a.calls
[Call(self=None, args=(1, 2, 3), kwargs={'b': 'c'})]
>>> calls is a.calls
True
```

---

<sup>1</sup> <http://www.martinfowler.com/bliki/TestDouble.html>

Changed in version 0.9.0: Renamed *history* option to *calls*. Renamed *call* option to *iscalled*. Added *callback* option. Added *extended* option.

`aspectlib.test.mock` (*return\_value*, *call=False*)

Factory for a decorator that makes the function return a given *return\_value*.

#### Parameters

- **return\_value** – Value to return from the wrapper.
- **call** (*bool*) – If `True`, call the decorated function. (default: `False`)

**Returns** A decorator.

**class** `aspectlib.test.Story` (*target*, *\*\*options*)

This a simple yet flexible tool that can do “capture-replay mocking” or “test doubles” <sup>1</sup>. It leverages aspectlib’s powerful weaver.

#### Parameters

- **target** (Same as for `aspectlib.weave`.) – Targets to weave in the *story/replay* transactions.
- **subclasses** (*bool*) – If `True`, subclasses of target are weaved. *Only available for classes*
- **aliases** (*bool*) – If `True`, aliases of target are replaced.
- **lazy** (*bool*) – If `True` only target’s `__init__` method is patched, the rest of the methods are patched after `__init__` is called. *Only available for classes*.
- **methods** (*list or regex or string*) – Methods from target to patch. *Only available for classes*

The `Story` allows some testing patterns that are hard to do with other tools:

- **Proxied mocks**: partially mock *objects* and *modules* so they are called normally if the request is unknown.
- **Stubs**: completely mock *objects* and *modules*. Raise errors if the request is unknown.

The `Story` works in two of transactions:

- **The story**: You describe what calls you want to mocked. Initially you don’t need to write this. Example:

```
>>> import mymod
>>> with Story(mymod) as story:
...     mymod.func('some arg') == 'some result'
...     mymod.func('bad arg') ** ValueError("can't use this")
```

- **The replay**: You run the code uses the interfaces mocked in the *story*. The `replay` always starts from a *story* instance.

Changed in version 0.9.0: Added in.

**replay** (*\*\*options*)

#### Parameters

- **proxy** (*bool*) – If `True` then unexpected uses are allowed (will use the real functions) but they are collected for later use. Default: `True`.
- **strict** (*bool*) – If `True` then an `AssertionError` is raised when there were *unexpected calls* or there were *missing calls* (specified in the story but not called). Default: `True`.
- **dump** (*bool*) – If `True` then the *unexpected/missing calls* will be printed (to `sys.stdout`). Default: `True`.

**Returns** A `aspectlib.test.Replay` object.

Example:

```
>>> import mymod
>>> with Story(mymod) as story:
...     mymod.func('some arg') == 'some result'
...     mymod.func('other arg') == 'other result'
>>> with story.replay(strict=False):
...     print(mymod.func('some arg'))
...     mymod.func('bogus arg')
some result
Got bogus arg in the real code !
STORY/REPLAY DIFF:
--- expected...
+++ actual...
@@ -1,2 +1,2 @@
 mymod.func('some arg') == 'some result' # returns
-mymod.func('other arg') == 'other result' # returns
+mymod.func('bogus arg') == None # returns
```

**class** aspectlib.test.Replay(?)

Object implementing the *replay transaction*.

This object should be created by Story's replay method.

**diff()**

Returns a pretty text representation of the unexpected and missing calls.

Most of the time you don't need to directly use this. This is useful when you run the *replay* in *strict=False* mode and want to do custom assertions.

**missing()**

Returns a pretty text representation of just the missing calls.

**unexpected** (*\_missing=False*)

Returns a pretty text representation of just the unexpected calls.

The output should be usable directly in the story (just copy-paste it). Example:

```
>>> import mymod
>>> with Story(mymod) as story:
...     pass
>>> with story.replay(strict=False, dump=False) as replay:
...     mymod.func('some arg')
...     try:
...         mymod.badfunc()
...     except ValueError as exc:
...         print(exc)
Got some arg in the real code !
boom!
>>> print(replay.unexpected())
mymod.func('some arg') == None # returns
mymod.badfunc() ** ValueError('boom!') # raises
```

We can just take the output and paste in the story:

```
>>> import mymod
>>> with Story(mymod) as story:
...     mymod.func('some arg') == None # returns
...     mymod.badfunc() ** ValueError('boom!') # raises
>>> with story.replay():
...     mymod.func('some arg')
```

```
...     try:
...         mymod.badfunc()
...     except ValueError as exc:
...         print(exc)
boom!
```

**TODO & Ideas**

---

## 9.1 Validation

```
class BaseProcessor(object):
    def process_foo(self, data):
        # do some work

    def process_bar(self, data):
        # do some work

class ValidationConcern(aspectlib.Concern):
    @aspectlib.Aspect
    def process_foo(self, data):
        # validate data
        if is_valid_foo(data):
            yield aspectlib.Proceed
        else:
            raise ValidationError()

    @aspectlib.Aspect
    def process_bar(self, data):
        # validate data
        if is_valid_bar(data):
            yield aspectlib.Proceed
        else:
            raise ValidationError()

aspectlib.weave(BaseProcessor, ValidationConcern)

class MyProcessor(BaseProcessor):
    def process_foo(self, data):
        # do some work

    def process_bar(self, data):
        # do some work

# MyProcessor automatically inherits BaseProcessor's ValidationConcern
```

---

## Changelog

---

### 10.1 Version 1.0

- Reworked the internals `aspectlib.test.Story` to keep call ordering, to allow dependencies and improved the serialization (used in the diffs and the missing/unexpected lists).

### 10.2 Version 0.9.0

- Changed `aspectlib.test.record`:
  - Renamed *history* option to *calls*.
  - Renamed *call* option to *iscalled*.
  - Added *callback* option.
  - Added *extended* option.
- Changed `aspectlib.weave`:
  - Allow weaving everything in a module.
  - Allow weaving instances of new-style classes.
- Added `aspectlib.test.Story` class for capture-replay and stub/mock testing.

### 10.3 Version 0.8.1

- Use simpler import for the `py3support`.

### 10.4 Version 0.8.0

- Change `aspectlib.debug.log` to use `Aspect` and work as expected with coroutines or generators.
- Fixed `aspectlib.debug.log` to work on Python 3.4.
- Remove the undocumented `aspectlib.Yield` advice. It was only usable when decorating generators.

## 10.5 Version 0.7.0

- Add support for decorating generators and coroutines in Aspect.
- Made aspectlib raise better exceptions.

## 10.6 Version 0.6.1

- Fix checks inside `aspectlib.debug.log` that would inadvertently call `__bool__`/`__nonzero`.

## 10.7 Version 0.6.0

- Don't include `__getattr__` in `ALL_METHODS` - it's too dangerous dangerous dangerous dangerous dangerous dangerous ... ;)
- Do a more reliable check for old-style classes in `debug.log`
- When weaving a class don't weave attributes that are callable but are not actually routines (functions, methods etc)

## 10.8 Version 0.5.0

- Changed `aspectlib.debug.log`:
  - Renamed *arguments* to *call\_args*.
  - Renamed *arguments\_repr* to *call\_args\_repr*.
  - Added *call* option.
  - Fixed issue with logging from old-style methods (object name was a generic “instance”).
- Fixed issues with weaving some types of builtin methods.
- Allow to apply multiple aspects at the same time.
- Validate string targets before weaving. `aspectlib.weave('mod.invalid name', aspect)` now gives a clear error (*invalid name is not a valid identifier*)
- Various documentation improvements and examples.

## 10.9 Version 0.4.1

- Remove junk from 0.4.0's source distribution.

## 10.10 Version 0.4.0

- Changed `aspectlib.weave`:
  - Replaced *only\_methods*, *skip\_methods*, *skip\_magicmethods* options with *methods*.

- Renamed *on\_init* option to *lazy*.
- Added *aliases* option.
- Replaced *skip\_subclasses* option with *subclasses*.
- Fixed weaving methods from a string target.
